## Author's Declaration

#### Abstract

I, Kiran Tabassum hereby state that my M.Phil thesis titled "Dynamic Key Dependent S-box for Symmetric Cryptosystem and its Application in Image Encryption" is my own work and has not been submitted previously by me for taking any degree from Capital University of Science and Technology, Islamabad or anywhere else in the country/abroad.

At any time if my statement is found to be incorrect even after my graduation, the University has the right to withdraw my M.Phil Degree.

## (Kiran Tabassum)

Registration No: MMT203009

## Plagiarism Undertaking

I solemnly declare that research work presented in this thesis titled "Dynamic Key Dependent S-box for Symmetric Cryptosystem and its Application in Image Encryption" is solely my research work with no significant contribution from any other person. Small contribution/help wherever taken has been duly acknowledged and that complete thesis has been written by me.

I understand the zero tolerance policy of the HEC and Capital University of Science and Technology towards plagiarism. Therefore, I as an author of the above titled thesis declare that no portion of my thesis has been plagiarized and any material used as reference is properly referred/cited.

I undertake that if I am found guilty of any formal plagiarism in the above titled thesis even after award of M.Phil Degree, the University reserves the right to withdraw/revoke my M.Phil degree and that HEC and the University have the right to publish my name on the HEC/University website on which names of students are placed who submitted plagiarized work.

Registration No: MMT203009

## Acknowledgement

First of all I would like to thanks Allah Almighty, The Beneficent, The Merciful, The most Kind, who gave me the strength to complete this work. Secondly, I am Thankful to my parents and siblings for always being supportive in my whole educational career. Further, I would like to thank those who helped me in achieving this goal and completing this task. I am profoundly grateful to my generous supervisor Dr. Rashid Ali for his encouragement. He was always there whenever I found any problem. I am grateful to him for helping and guidance. His suggestions and guidance helped me in completing the thesis. I would like to thank all of my friends for motivating me during my degree program. Mostly, I would like to thank Phd scholar Tahir Ali also helped me a lot and guided me whenever I needed it.

## Abstract

An S-box is a main component of many symmetric cryptographic algorithms. The most important characteristics of an S-box is to add non-linearity in the corresponding encryption scheme. The design of S -boxes is to increase the confusion ability of the cipher. Some researchers purposed different S-boxes based on different techniques. In this thesis, first an S-box based on simple mathematics operation is reviewed. The S-box is constructed using MATLAB, then the generated S-box is used for the image encryption scheme. In the scheme a compound chaotic map namely, the tent-logistic map is used. The tent logistic map is used for the generation of chaotic sequence. The secret key used in the construction of the S-box is further extended for using it as the initial conditions of the compound chaotic map. Results and security analysis demonstrate the good performance of the algorithm as a secure communication method for images.

## Chapter 1

## Introduction

From ancient times to the present day, cryptography ensures security during communication. The word cryptography comes from the Greek kryptos, which means hidden. The "crypt-" means "hidden", and the "-graphy" means "writing". Cryptography is the science of secure secret communication so that no third party can read or modify the information. Cryptography converts the secret messages into non readable form or secret code with the help of algorithm. The converted message is called ciphertext and the original message is called plaintext. A process which converts plaintext into ciphertext is called as Encryption and an algorithm which is used in encryption is known as Encryption algorithm. A process which converts ciphertext back to its plaintext is called as Decryption and an algorithm which is used in decryption is known as Decryption algorithm. For the encryption and decryption, cryptographic schemes need some important information which is shared between both sender and receiver, is called a Key [1]. A cryptographic scheme that consists of a message, a ciphertext, a key, an encryption algorithm and decryption algorithm is called a cryptosystem. On the basis of cryptosystem, the cryptography is divided in the following two types. Name as, the Symmetric Key Cryptography and the Public Key Cryptography.

In Symmetric Key Cryptography, a similar key is used for both encryption and decryption. To encrypt and decrypt all messages, both the sender and the receiver must know the secret key. Data Encryption Standard [1], Advanced Encryption

Standard [1], Triple Data Encryption Standard [2], RC4 [1], RC6, Blowfish [2] are examples of symmetric key cryptography. In Public Key Encryption, public and private keys are used separately for encryption and decryption. Since the public key is meant for widespread use, everyone on the network has access to it. One needs to be aware of the recipient's public key in order to encrypt the plaintext. Using their own private key, only the authorised person is able to decrypt the encrypted text. The public is not allowed to see the private key. RSA [2] and ElGamal [3] are examples of public key cryptography.

### 1.1 S-boxes in Cryptography

Substitution box is an essential component of symmetric key algorithms that performs substitution in cryptography. Substitution boxes are essentially Boolean vectorial functions given as look-up tables. An S-box takes a small block of bits and replaces them with another bit block. For efficient decryption, this substitution must be one to one. The substitution box usually takes $m$ input bits and transforms into $n$ output bit. An $m \times n$ S-box can be viewed as a look up table of $2^{m}$ words of $n$ bits each. To strengthen the cryptosystem, an S-box must be designed in such a way that every output bit will depend on each input bit.

A symmetric key cryptosystem has stream cipher or block cipher. A block cipher converts whole block of plaintext into block of ciphertext using the secret key at a time whereas stream cipher encrypts one bit data at a time. So a block cipher has two basic requirement, size of block and size of key. The block ciphers are based on the Shannon's theory of confusion and diffusion that is also implemented in Substitution Permutation networks. Such networks essentially consist of a number of mathematical operations which are interconnected. It takes plaintext and key as input and apply many rounds of S-box to get desired ciphertext. The inverse Sbox is used with the same key for decryption to obtain plaintext. Data Encryption Standard and Advanced Encryption Standard are examples of SPN cryptosystem.

The majority of currently used cipher blocks are build on the static natured Sboxes, which is a fundamental weakness in symmetric ciphers. As a result, the most serious flaw in symmetric cryptosystem is predetermined (fixed) substitution since it results in insecure ciphers [4] due to the fixed and predefined qualities of diffusion and confusion. The primary building block of security in an encryption scheme is substitution, despite the fact that permutation has its own effects.

Furthermore, predefined (static) S-boxes do not depend on the secret key, so these static S-boxes are responsible for easy doorways for attackers to launch algebraic attacks. Therefore, scaling the established S-box structure with dynamic strategies is the next challenge for today's symmetric cryptosystem in order to defend against linear and differential attacks as discussed in [5] and [6]. By generating S-boxes dynamically, the strength of ciphers can be increased as stated in $[7,8]$.

### 1.2 Image Encryption in Cryptography

An image is something you can see, but its not physically there. It can be a photograph, a painting, a picture on a television or computer screen or other twodimensional representation. In a world where multimedia technology uses digital images extensively, maintaining user privacy is more crucial than ever. Image encryption is the process of encoding an image with the help of some encryption algorithm. Image encryption is crucial to ensuring the user's security and privacy and to guard against any unauthorised user access. Applications for image and video encryption can be found in a variety of industries, telemedicine, medical imaging, multimedia systems, the internet, and military correspondence [9]. So, the transmitting and receiving images from open platform such as the internet may not always be safe. In order to assure secure image transfer, a secure image sharing technique is needed. A secure image sharing approach that ensures secure image transmission is being achieved with the help of cryptography. Due to its increasing popularity and necessity, a variety of image encryption techniques have been created. Because of features like high correlation analysis, large data capacities, and
other characteristics, images are fundamentally different from texts. Therefore, well-known techniques like the AES and the IDEA are always not effective.

### 1.3 Literature Review

Numerous S-boxes have been designed by researchers, and numerous new construction methods have been suggested. Several attempts have been made in earlier years to replace the static AES S-box structure with dynamic features.

Kazlauskas et al. [10] designed the S-boxes by carrying out different operations on round key.

Fahmy et al. [11] used GNU-C and ISO-C as the two parameters to create the symmetric S-box, replacing the inverse S-box with a new transformation called the shift row transformation.

Agarwal et al. [12] generated 256 key-dependent S-boxes using the affine values ranging from 0 to 255 from the list of 30 irreducible polynomials.

Sahoo et al. [13] employed the affine transformation to construct the static Sboxes.

Nadaf and Desai [14] used the construction strategy of the multi-operation S-box, which also depends on the static AES S-box. Anees and Chen [15] also used the similar construction strategy.

Manjula and Mohan [16] constructed the dynamic S-boxes in which the static S-box was left rotating based on the resulting 16 -byte values of round key after performing the exclusive OR operation.

Balajee and Gnanasekar [17] used the pseudo random numbers to generate dynamic S-box values. Alabaichi and Salih [18] also used the similar strategy. A detailed analysis demonstrates that the some S-box approaches are better than other.

Ejaz et al. [19] proposed a secure key dependent dynamic substitution method for symmetric cryptosystems. The generated S-box has dynamic and unique values at each time during the execution and have strong cryptographic properties and randomness and achieved the basic goal of security of symmetric cryptosystems, which details are discused later in Chapter 3.

Recent studies have shown that chaotic-based S-box image encryption has greatly increased security. Similarly, researchers have designed several image encryption techniques in which some are based on different chaotic maps and some are based on permutation and substitution. With the passage of time, many new techniques have been proposed for building strong image encryption techniques.

Pareek et al. [20] have proposed an image encryption scheme using the logistic map.

Zhang et al. [21] suggested chaotic image encryption method based on a key stream buffer and circular substitution box. To generate random numbers, the system has used the logistic map and piecewise linear chaotic map.

Sheela et al. [22] proposed image encryption based on a modified Henon map using hybrid chaotic shift transform.

Supriyo et al. [23] proposed image encryption technique using permutation and substitution. The Arnold's Cat map was used in the construction of the image permutation technique and the logistic map used to create an S-box which was further used for key expansion.

Tyagi and Chaudhary [24] proposed method for image encryption by using two skew chaotic map and external key of 128-bit. The initial conditions for both the skew tent maps are derived using the external secret key.

Li et al. [25] suggested a technique that jointly permutes and diffuses (JPD) the pixels. Similarly, there are many other techniques for image encryption which are developing day by day for generation the strong cipher.

### 1.4 Thesis Contribution

The objective of this thesis is to study the scheme of Ejaz et al. [19] for the construction of strong key dependent dynamic S-box and this key dependent Sbox is used in image encryption scheme. S-box is only nonlinear component of block cipher. Many S-boxes are generated from different scheme. In [19] S-box is generated with only simple mathematical operation like circular shift, XOR and nibble swap. This scheme is implemented in MATLAB. This scheme is used to generate various S -boxes and the cryptographic properties of these S -boxes are analysed with the help of tool [26]. The strength of S-boxes are measured on the basis of certain properties that are discussed in Chapter 2. The generated different key dependent S-boxes is also present in Chapter 3. Finally, we applied this S-box in image encryption scheme. We use compound chaotic map for image encryption. A chaotic map is an evaluation map that exhibits some sort of chaotic behavior (e.g.randomness). The method is effectively implemented to encrypt and decrypt the image in MATLAB and the security analysis of scheme, which includes key sensitivity and statistical analysis, is also determined.

### 1.5 Thesis Layout

The dessertation is composed as follow:

- Chapter 2 describes the basic definitions, fundamental ideas, mathematical background and Boolean function that involve in the construction and analysis of S-box.
- Chapter 3 describes the construction of dynamic key dependent secure S-boxes by using simple mathematical functions or operations and the comparison between newly generated S-boxes of the proposed method. All the calculation are obtained with the help of MATLAB.
- Chapter 4 describes the image encryption technique, by using obtained key dependent S-box and compound chaotic map. With the help of MATLAB, all the calculation are obtained.
- Chapter 5 includes the conclusion of the thesis.

## Chapter 2

## Preliminaries

This chapter describes the definitions, fundamental ideas, mathematical background and basic concepts of group theory and algebra that involve in the construction and analysis of S-box.

### 2.1 Cryptography

Cryptography is the science of secure secret communication so that no third party can read or modify the information. Cryptography converts the messages into non readable form with the help of algorithm. In cryptography, there are number of techniques which are useful for security purpose. For converting the messages or data into secret codes, we need a scheme or system. Such system is known as Cryptosystem [1]. A cryptosystem consist of five basic components:

- Plaintext: It is the original or readable form of message.
- Ciphertext: It is the converted or unreadable form of message.
- Encryption Algorithm: It converts plaintext into ciphertext.
- Decryption Algorithm: It converts ciphertext into plaintext.
- Key: It is the special information used in encryption and decryption algorithms which must be known to sender and receiver.

The cryptography is divided in the following two types.

- Symmetric Key Cryptography
- Public Key Cryptography

### 2.1.1 Symmetric Key Cryptography

In this type of encryption mechanism, the key used for encryption is same as the key used for decryption. Therefore, it is important to share the key before the transmission of information [1]. The sender and receiver must have the secret key so they can encrypt and decrypt all messages. There are several symmetric key algorithms like Data Encryption Standard (DES) [2], Advanced Encryption Standard (AES) [1, 2], Triple Data Encryption Standard (Triple DES) [2], RC4 [27], RC6, Blowfish [2]. Key sharing is the main flaws of symmetric key cryptography.

### 2.1.2 Public Key Cryptography

For public key cryptography, two different keys are used for encryption and decryption. These are private key and public key. The public key is for general use, and it is available to everyone on the network. Anyone who wants to encrypt the plaintext must know the public key of the receiver. Only the authorized person who has private key can decrypt the encrypted text. The private key is always kept secret from the outside world. RSA [2] and ElGamal [3] are examples of public key cryptography. The drawback of public key cryptography is that it is slower than symmetric key cryptography but it resolves key sharing issue of symmetric key cryptography. A symmetric key cryptosystem has either block cipher or stream cipher.

## Definition 2.1.1. (Stream Cipher)

A stream cipher is symmetric key cipher whose each bit of data is sequentially encrypted using one bit of the key.

## Definition 2.1.2. (Block Cipher)

A block cipher is an encryption/decryption scheme in which each block of plaintext is processed as a whole and used to produce another equal-length block of ciphertext.

### 2.2 Mathematical Background

In this section, some basic principles of group theory are introduced to understand the explanation for the formation and success of the S-boxes.

## Definition 2.2.1.

Let $G$ be a non-empty set with binary operation $(*)$ on $G$. Then $(G, *)$ is called a Group, if the following properties are satisfied:

1. Closure: For all $c, d \in G, c * d \in G$.
2. Associative: For all $c, d, e \in G,(c * d) * e=c *(d * e)$.
3. Identity: For all $c \in G$, there exists an element $f \in G$ such that

$$
c * f=f * c=c
$$

4. Inverse: For each $g \in G$, then there exist an element $g^{-1} \in G$ such that

$$
g * g^{-1}=g^{-1} * g=f
$$

Moreover, $G$ is said to be Abelian or Commutative Group, if the group holds

$$
c * d=d * c \quad \text { for all } c, d \in G
$$

## Example 2.2.2.

Following are some examples of group:

1. Set of integers $\mathbb{Z}$ is a group with respect to usual addition operation of integer.
2. Set of all invertible matrices of order $n \times n$ with ordinary matrix multiplication forms a group.
3. Set of real number $\mathbb{R}$ is a group under addition.
4. The set $\mathbb{R}$ and set of integers $\mathbb{Z}$ are the examples of abelian groups with respect to addition.
5. The set of $\mathbb{R} \backslash\{0\}$ is an example of an abelian group with respect to multiplication.

## Definition 2.2.3.

A non-empty set $\mathbb{F}$ with two binary operation addition (+) and multiplication (.) is called a Field, if it satisfies the following properties:

1. $(\mathbb{F},+)$ is commutative group.
2. ( $\mathbb{F} \backslash\{0\},$.$) is commutative group.$
3. Distributivity of multiplication over addition.

For all $c, d, e \in \mathbb{F}$

$$
c \cdot(d+e)=(c \cdot d)+(c \cdot e)
$$

Moreover, a field that contains finitely many elements is called Finite Field.

## Example 2.2.4.

Following are some examples of field:

1. Set of real numbers $\mathbb{R}$ are field under usual addition and multiplication.
2. Set of complex numbers $\mathbb{C}$ are field under usual addition and multiplication.
3. Set of integer $\mathbb{Z}$ is not a field as there are no multiplicative inverses in $\mathbb{Z}$.

## Definition 2.2.5.

A finite field in which the number of elements are of the form $p^{n}$ is called Galois Field where $p$ is prime and $n$ is positive integer. It is denoted by $G F\left(p^{n}\right)$.

The elements of Galois field $G F\left(p^{n}\right)$ is defined as [28]
$G F\left(p^{n}\right)=\{0,1,2, \ldots ., p-1\} \cup\{p, p+1, p+2, \ldots, p+p-1\}$

$$
\cup\left\{p^{2}, p^{2}+1, p^{2}+2, \ldots, p^{2}+p-1\right\} \cup \ldots
$$

$$
\cup\left\{p^{n-1}, p^{n-1}+1, p^{n-1}+2, \ldots, p^{n-1}+p-1\right\}
$$

The order of the Galois field is given by $p^{n}$ and $p$ is the characteristic of the field whereas characteristics of the field is defined as the minimum number of times the multiplicative identity (one) must be used in a sum to obtain the additive identity (zero).

From the perspective of cryptography, one will focus on the following cases:

- $G F(p), n=1$
- $G F\left(2^{n}\right), p=2$

All polynomials of degree less than $n$ with coefficients from $G F(p)$ are the elements of $G F\left(p^{n}\right)$. There are 256 elements in the finite field $G F\left(2^{8}\right)$.

## Definition 2.2.6.

In mathematics, Circular Shift is the operation of rearranging the entries in a tuple, either by moving the last entry to the first place, while moving all the other entries to the next place, or by performing the operation inverse. Circular shifts are often used in cryptography to rearrange sequences of bits.

There are two types of circular shift, one is left circular shift and other is right circular shift which are discussed below:

## 1 Left Circular Shift

Left circular shift of $n$ bits moves the first bits in the ending of the bit string while moving all other bits to the previous position.

## Example 2.2.7.

Table 2.1 are examples of left circular shift:
Table 2.1: Left Circular Shift

| $\mathbf{8}$ Bit Sequence | Shift by $\mathbf{3}$ |
| :--- | :--- |
| 10010111 | 10111100 |
| 11100101 | 00101111 |
| 01111001 | 11001011 |
| 11001101 | 01101110 |
| 01001101 | 01101010 |

## 2 Right Circular Shift

Right circular shift of $n$ bits moves the last bits in the beginning of the bit string while changing all other bits to the next position.

## Example 2.2.8.

Table 2.2 are examples of right circular shift:
Table 2.2: Right Circular Shift

| $\mathbf{8}$ Bit Sequence | Shift by $\mathbf{3}$ |
| :--- | :--- |
| 11110010 | 01011110 |
| 01100101 | 10101100 |
| 00101111 | 11100101 |
| 10111001 | 00110111 |
| 00111001 | 00100111 |

## Definition 2.2.9.

In the nibble swap, the nibble is four binary bits or "half a byte". The terms "byte" almost always refer to 8 bits. In the Nibble Swap operation, a byte is split from the middle, into two nibbles, and then the two nibbles change position with each other. Equivalently, swap the two hexadecimal numbers.

## Example 2.2.10.

Consider a number $(93)_{10}$ in binary representation is $(01011101)_{2}$ and in hexadecimal form is $(5 D)_{16}$.

It has two nibbles 0101 and 1101.

After swapping the nibbles, we get $(11010101)_{2}$ which is $(213)_{10}$ in decimal form and $(D 5)_{16}$ in hexadecimal form.

### 2.3 Boolean Function

Boolean function is define as $f: G F\left(2^{m}\right) \rightarrow G F(2)$ where $m$ is non-negative integer. In which $m$ tuples $\left\{b_{1}, b_{2}, b_{3} \ldots, b_{m}\right\} \in G F\left(2^{m}\right)$ as input and produces only one of the two output bits $\{0,1\} \in G F(2)[19]$. By using Boolean function, output values of Boolean can be determined with the help of some logical calculations of input values of Boolean. Boolean function has only the two possible outcome: one is true (one) and the other is false (zero). These functions are useful for designing electronic circuits, integrated circuits and digital computer chips. These functions also play a significant role for designing a substitution boxes (S-box) in cryptography.

A Boolean function can be expressed in two different ways.

- Truth Table (TT)
- Algebraic Normal Form (ANF)

## Definition 2.3.1.

Truth Table represents the possible outcomes of a Boolean function in tabular form. The first two columns show the possible input and the last column shows the executed output of function. Boolean function $f$ can be represented as a binary vector of size $\left(2^{m} \times 1\right)$, with entries $f(b)$ indexed by the vectors $b \in G F\left(2^{m}\right)$.

## Example 2.3.2.

Consider the Boolean function $f=b_{1} \oplus b_{2}$ of two variables $b_{1}$ and $b_{2}$. Truth Table of $m=2$ is shown below in Table 2.3.

Table 2.3: Truth Table for XOR

| $b_{1}$ | $b_{2}$ | $f$ |
| :---: | :---: | :---: |
| 0 | 0 | 0 |
| 0 | 1 | 1 |
| 1 | 0 | 1 |
| 1 | 1 | 0 |

## Example 2.3.3.

Consider the Boolean function $f=b_{1} \cdot b_{2}$ of two variables $b_{1}$ and $b_{2}$. Truth Table of $m=2$ is shown below in Table 2.4.

Table 2.4: Truth Table for AND

| $b_{1}$ | $b_{2}$ | $f$ |
| :---: | :---: | :---: |
| 0 | 0 | 0 |
| 0 | 1 | 0 |
| 1 | 0 | 0 |
| 1 | 1 | 1 |

## Example 2.3.4.

Consider a mapping $f$ : $G F\left(2^{4}\right)$ to $G F(2)$ given by

$$
f\left(b_{1}, b_{2}, b_{3}, b_{4}\right)=b_{1} b_{2} b_{3} \oplus b_{2} b_{3} b_{4} \oplus b_{1}
$$

For all possible values, the input bits $b_{1}, b_{2}, b_{3}$ and $b_{4}$, the output bit $f$ are shown in Table 2.5.

Table 2.5: Truth Table of Boolean Function

| $b_{1}$ | $b_{2}$ | $b_{3}$ | $b_{4}$ | $f$ |
| :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 0 | 0 |
| 0 | 0 | 0 | 1 | 0 |
| 0 | 0 | 1 | 0 | 0 |
| 0 | 0 | 1 | 1 | 0 |
| 0 | 1 | 0 | 0 | 0 |
| 0 | 1 | 0 | 1 | 0 |
| 0 | 1 | 1 | 0 | 0 |
| 0 | 1 | 1 | 1 | 1 |
| 1 | 0 | 0 | 0 | 1 |
| 1 | 0 | 0 | 1 | 1 |
| 1 | 0 | 1 | 0 | 1 |
| 1 | 0 | 1 | 1 | 1 |
| 1 | 1 | 0 | 0 | 1 |
| 1 | 1 | 0 | 1 | 1 |
| 1 | 1 | 1 | 0 | 0 |
| 1 | 1 | 1 | 1 | 1 |

## Definition 2.3.5.

Boolean function $f: G F\left(2^{m}\right) \rightarrow G F(2)$ of Algebraic Normal Form(ANF) described in the following form of polynomial.

$$
\begin{gathered}
f\left(b_{1}, b_{2}, \ldots, b_{m}\right)=a_{0} \oplus a_{1} b_{1} \oplus a_{2} b_{2} \oplus \ldots \oplus a_{m} b_{m} \oplus \\
a_{1,2} b_{1} b_{2} \oplus \ldots \oplus a_{m-1, m} b_{m-1} b_{m} \oplus \ldots \oplus \\
a_{1,2 \ldots m} b_{1} b_{2}, \ldots, b_{m}
\end{gathered}
$$

where $b_{1}, b_{2}, \ldots, b_{1,2, \ldots m} \in\{0,1\}^{m}$.

The ANF representation of Boolean function is most commonly used in cryptography. Boolean functions are widely used due to its unique properties. In study of S-boxes and Boolean functions, ANF plays an important role.

Consider the Boolean function $f$ of two variables $b_{1}$ and $b_{2}$. The ANF of 'XOR' Boolean function is represented as

$$
f\left(b_{1}, b_{2}\right)=b_{1} \oplus b_{2} \oplus b_{1} b_{2}
$$

### 2.3.1 Application of Boolean Function in S-boxes

In cryptography, Boolean functions are important element for the construction of S-box. The function $P$ defined as

$$
P: G F\left(2^{n}\right) \rightarrow G F\left(2^{m}\right)
$$

takes $n$ bits as input and returns $m$ output bits where $m>1$ is a vectorial Boolean function. Basically, an S-box is a vectorial Boolean function.

## Definition 2.3.6.

The sequence of form $\left\{(-1)^{f\left(\beta_{0}\right)},(-1)^{f\left(\beta_{1}\right)}, \ldots,(-1)^{f\left(\beta_{2}{ }^{n}-1\right)}\right\}$ is known as Sequence of Boolean function. A sequence in which ones and minus ones or zeros has equal number known as balanced sequence whereas a sequence which has unequal number of ones and minus ones or zero known as unbalanced sequence.

## Example 2.3.7.

Consider the following Boolean function which has three $b_{1}, b_{2}$ and $b_{3}$ as input bits.

$$
f\left(b_{1}, b_{2}, b_{3}\right)=b_{3} \oplus b_{1} b_{2}
$$

and it is shown in Table 2.6.

The sequence of Boolean function can be written as:

Table 2.6: Truth Table of $G F\left(2^{3}\right)$

| $b_{1}$ | $b_{2}$ | $b_{3}$ | $b_{1} b_{2}$ | $f$ |
| :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 0 | 0 |
| 0 | 0 | 1 | 0 | 1 |
| 0 | 1 | 0 | 0 | 0 |
| 0 | 1 | 1 | 0 | 1 |
| 1 | 0 | 0 | 0 | 0 |
| 1 | 0 | 1 | 0 | 1 |
| 1 | 1 | 0 | 1 | 1 |
| 1 | 1 | 1 | 1 | 0 |

$\left\{(-1)^{f\left(\beta_{0}\right)},(-1)^{f\left(\beta_{1}\right)},(-1)^{f\left(\beta_{2}\right)},(-1)^{f\left(\beta_{3}\right)},(-1)^{f\left(\beta_{4}\right)},(-1)^{f\left(\beta_{5}\right)},(-1)^{f\left(\beta_{6}\right)},(-1)^{f\left(\beta_{7}\right)}\right\}$
$\left\{(-1)^{0},(-1)^{1},(-1)^{0},(-1)^{1},(-1)^{0},(-1)^{1},(-1)^{1},(-1)^{0}\right\}$
$\{1,-1,1,-1,1,-1,-1,1\}$

It contains equal numbers of 1 s and -1 s. Hence, the sequence of Boolean function is balanced.

## Definition 2.3.8.

A Boolean mapping $f: G F\left(2^{m}\right) \rightarrow G F(2)$ which can be written in the form of linear combination is known as Linearity, expressed as

$$
f\left(x_{1}, x_{2}, \ldots, x_{m}\right)=d_{1} x_{1} \oplus d_{2} x_{2} \oplus \ldots \oplus d_{m} x_{m}
$$

where $d_{1}, d_{2} \ldots, d_{m} \in 2^{m}$ and the symbol used for XOR operation is $\oplus$ and linear combination of two Boolean functions $f(x), g(x)$ is define as

$$
(f \oplus g) x=f(x) \oplus g(x)
$$

## Definition 2.3.9.

A Boolean mapping $f: G F\left(2^{m}\right) \rightarrow G F(2)$ which is combination of linearity and the constant is known as Affine Function, expressed as

$$
f\left(x_{1}, x_{2}, \ldots, x_{m}\right)=d_{1} x_{1} \oplus d_{2} x_{2} \oplus \ldots \oplus d_{m} x_{m} \oplus d_{0}
$$

For an Affine cipher, a Boolean function over modulo $e$ is used. It is a basic substitution cipher. Due to less security, affine cipher can easily breakable.

This cipher performs the addition and multiplication using the function;

$$
f(x)=(B x \oplus D) \quad \bmod e
$$

where $B$ and $D$ are key for the cipher. It is used for the encryption.

## Definition 2.3.10.

The number of non-zero digits in a binary sequence is called Hamming Weight. It is represented by $H(w)$, where $w \in G F\left(2^{m}\right)$

## Example 2.3.11.

For $m=8$, take a sequence

$$
w=(10100111)
$$

in which the number of zeros is three and the number of ones is five.

Thus Hamming weight is

$$
w=(10100111)=H(10100111)=5
$$

## Definition 2.3.12.

Hamming Distance between two Boolean functions $k(u)$ and $l(u)$ with mapping $k(u), l(u): G F\left(2^{m}\right) \rightarrow G F(2)$ is define as:

$$
d(k, l)=H(k(u) \oplus l(u))
$$

$$
k(u) \oplus l(u)=k\left(u_{0}\right) \oplus l\left(u_{0}\right) \oplus k\left(u_{1}\right) \oplus l\left(u_{1}\right) \oplus \ldots \oplus k\left(u_{2^{m}-1}\right) \oplus l\left(u_{2^{m}-1}\right)
$$

where $u=\left(u_{0}, u_{1}, \ldots, u_{2^{m}-1}\right) \in G F\left(2^{m}\right)$.

Hamming distance is also defined as the number of bit positions in which the two bits are different. For calculation of Hamming distance, we perform the XOR operation and then count the number of $1 s$ in the result.

## Example 2.3.13.

Consider the two Boolean functions

$$
\begin{aligned}
& k(u)=10011111 \\
& l(u)=10101011
\end{aligned}
$$

And after taking XOR operation, we get

$$
k(u) \oplus l(u)=00110100
$$

Thus, the Hamming distance is $d(k, l)=3$

## Example 2.3.14.

Consider the two Boolean function $k(u)$ and $l(u)$ with $u_{1}, u_{2}$ and $u_{3}$ as input bits where

$$
k(u)=u_{1} u_{2} u_{3}, \quad l(u)=u_{1} \oplus u_{2} u_{3}
$$

The Hamming distance of Boolean functions are

$$
d(k, l)=H(k(u) \oplus l(u))
$$

also write as

$$
d(k, l)=H\left(\left(u_{1} u_{2} u_{3}\right) \oplus\left(u_{1} \oplus u_{2} u_{3}\right)\right)
$$

the calculation of Hamming distance are shown in Table 2.7

Table 2.7: Hamming Distance of Boolean Function

| $u_{1}$ | $u_{2}$ | $u_{3}$ | $k=u_{1} u_{2} u_{3}$ | $l=u_{1} \oplus u_{2} u_{3}$ | $k(u) \oplus l(u)$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 0 | 0 | 0 |
| 0 | 0 | 1 | 0 | 0 | 0 |
| 0 | 1 | 0 | 0 | 0 | 0 |
| 0 | 1 | 1 | 0 | 1 | 1 |
| 1 | 0 | 0 | 0 | 1 | 1 |
| 1 | 0 | 1 | 0 | 1 | 1 |
| 1 | 1 | 0 | 0 | 1 | 1 |
| 1 | 1 | 1 | 1 | 0 | 1 |

Thus, the Hamming distance is $d(k, l)=5$

## Definition 2.3.15.

The correlation measurement between Boolean function $g$ and all the linear combinations is called the Walsh Transform. The Boolean function of the Walsh transform is defined as:

$$
\begin{equation*}
W T_{g}(\beta)=\sum_{\beta \in G F\left(2^{m}\right)}(-1)^{g(u) \oplus \beta \cdot u} \tag{2.1}
\end{equation*}
$$

for all $u \in G F\left(2^{m}\right)$.

### 2.4 Substitution Boxes

Substitution box (S-box) is an necessary component of symmetric key algorithms that performs substitution. An S-box takes a small bits block and replaces them with another bit block. For efficient decryption, this substitution must be one to one. The substitution box usually takes $m$ input bits and transforms into $n$ output bit. To strengthen the cryptosystem, an S-box must be designed in such a way that every output bit will depend on each input bit. The non-linearity is
most important feature of the substitution box. Because S-box are non-linear so that it provides security in particular against linear cryptanalysis.

### 2.4.1 Characteristics of S-box

In cryptosystem, S-box is only the highly nonlinear Boolean function. Actually, there are two main reasons for studying the S-box design:

- Designing new Ciphers

S-box design is the most important area for designing a new cipher, due to the fact it is the solely nonlinear part of the system. The strength of cipher depends on this part. As with development of cryptography, hackers are also creating new methods of attacks, so S-box design have to be secured in advance to assurance cipher security.

## - Private use of S-Box Design

Adversaries used the back-doors to generate key for certain ciphers such as AES, therefore, each agency and particularly governments prefer to have a secure device only relevant to their agency with a more safety layer which is feasible solely if they design their S-boxes for their particular system.

### 2.4.2 Classification of S-boxes

There are three types of S-box.

## - Straight S-box

A Straight S-box takes an input and produces output of the similar size. This type of S-box had been recommended by Rijndeel cipher. It is the easiest and common category of S-box. Advanced Encryption Standard is an example of such S-box.

- Expanded S-box

It collects lesser bits as input and create an output of more bits. Such S-box can be build by duplicating some input or output bits.

- Compressed S-box

This type of S-box takes more input bits and produce lesser output bits. Example of this type of S-Box is Data Encryption Standard in which 6 bits of input are taken as one block of input and 4 bits in one block are returned as output block.

### 2.4.3 General Properties of S-Box

Substitution boxes (S-Boxes) are an important part of many cryptosystem. Its perform substitution in cryptography, so it should satisfy the following properties for developing a strong S-box. Some properties of the strong S-Box are given below.

Definition 2.4.1.

A sequence of Boolean function $g$ is called Balanced if the occurrence of both zeros and ones are equal.

## Example 2.4.2.

Consider the Boolean function with mapping

$$
G F\left(2^{4}\right) \rightarrow G F(2)
$$

such that

$$
g\left(b_{1}, b_{2}, b_{3}, b_{4}\right)=b_{1} \oplus b_{2} \oplus b_{3} b_{4}
$$

where $b_{1}, b_{2}, b_{3}$ and $b_{4}$ are taken as inputs bits which are given in Table 2.8.

In Table 2.8, the last column has eight zeros and the eight ones. Thus, the sequence $g$ is balanced.

Table 2.8: Truth Table of $G F\left(2^{4}\right)$

| $b_{1}$ | $b_{2}$ | $b_{3}$ | $b_{4}$ | $b_{3} b_{4}$ | $g$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 0 | 0 | 0 |
| 0 | 0 | 0 | 1 | 0 | 0 |
| 0 | 0 | 1 | 0 | 0 | 0 |
| 0 | 0 | 1 | 1 | 1 | 1 |
| 0 | 1 | 0 | 0 | 0 | 1 |
| 0 | 1 | 0 | 1 | 0 | 1 |
| 0 | 1 | 1 | 0 | 0 | 1 |
| 0 | 1 | 1 | 1 | 1 | 0 |
| 1 | 0 | 0 | 0 | 0 | 1 |
| 1 | 0 | 0 | 1 | 0 | 1 |
| 1 | 0 | 1 | 0 | 0 | 1 |
| 1 | 0 | 1 | 1 | 1 | 0 |
| 1 | 1 | 0 | 0 | 0 | 0 |
| 1 | 1 | 0 | 1 | 0 | 0 |
| 1 | 1 | 1 | 0 | 0 | 0 |
| 1 | 1 | 1 | 1 | 1 | 1 |

## Definition 2.4.3.

Bijection is a mapping, which gives a unique output with the each input bits. Let $n$ be the possible input bits such as $(0,1)^{n}$, there exists a unique output bit. All the output vector must appear once. For calculating the bijective property a method was introduced for the $n \times n$ [29] S-boxes. An $n \times n$ S-boxes are said to satisfy the bijective property if for $(1 \leq j \leq n)$ the Boolean functions $g_{j}$ of S are such that:

$$
\begin{equation*}
H\left(\sum_{j=1}^{n} a_{j} g_{j}\right)=2^{n-1} \tag{2.2}
\end{equation*}
$$

where $a_{j} \in\{0,1\}$ for $\left(a_{1}, a_{2}, \ldots, a_{n}\right) \neq(0,0, \ldots, 0)$ and $H$ is the Hamming weight.

The Condition 2.2 guarantees that every Boolean function $g_{j}$ and all their combination are balanced.

## Definition 2.4.4.

The Correlation Immunity [30] of a Boolean function denotes the independence size between the linear combination of input and output bits. By using the relationship between Walsh transform and Hamming weight of its input, functional order can be determine.

When $W T_{g}(\beta)=0$, and $1 \leq H(w) \leq \mathrm{p}$, a Boolean function is said to have correlation immunity.

## Definition 2.4.5.

Algebric Immunity of two Boolean functions $g(u)$ and $h(u)$ is defined as the lowest degree of non-zero function $h$ such that either

$$
(g+1) h=0 \text { or } g \cdot h=0
$$

where the function $h$ for which $g \cdot h=0$ is called annihilator of $g$ [31].

## Definition 2.4.6.

The Absolute Indicator of Boolean function $g(u)$ is defined as the maximum absolute value of autocorrelation, which are:

$$
\triangle_{g}=\max \left|\triangle_{g}(d)\right| \quad \text { where } d \in G F\left(2^{n}\right)
$$

And the Autocorrelation of Boolean function $g(u)$ is defined as:

$$
\triangle_{g}(d)=\sum(-1)^{g(u)+g(u+d)} \quad \text { where } u \in G F\left(2^{n}\right)
$$

The Sum of Square Indicator of Boolean function $g(u)$ also derived from the autocorrelation function $\triangle_{g}(d)$ which are

$$
\sigma_{g}=\sum_{d \in G F\left(2^{n}\right)}\left(\triangle_{g}(d)\right)^{2}
$$

## Definition 2.4.7.

An Algebraic degree is associated with the nonlinearity measures. An algebric degree of Boolean function $g(u)$ is defined as the highest degree of a function $g$, which are

$$
\operatorname{deg}(g)=n-1
$$

Higher algebraic degree are more better than the lower algebraic degree.

## Definition 2.4.8.

The Non-linearity of a Boolean function with mapping $g(u): G F\left(2^{n}\right) \rightarrow G F(2)$ is defined as the minimum hamming distance of g from the set of all $n$-variable affine functions.

$$
N L(g)=\min d(k, l)
$$

Nonlinearity of Boolean function $g$ can be shown by using Walsh transform from the following formula

$$
N L(g)=2^{n-1}\left(1-2^{-n}\right) \max _{\beta \in G F\left(2^{n}\right)}\left|W H T_{g}(\beta)\right|
$$

Thus a Boolean function $g$ which is a maximally nonlinear is known as bent function.

## Example 2.4.9.

Let $u_{1}$ and $u_{2}$ are input bits and $g(u)$ is a Boolean function such that

$$
g\left(u_{1}, u_{2}\right)=u_{1} \oplus u_{2}
$$

Truth Table is given below:
Table 2.9: Truth Table

| $u_{1}$ | $u_{2}$ | $g(u)$ | 0 | $u_{1} \oplus u_{2}$ | $g(u) \oplus 0$ | $g(u) \oplus u_{1}$ | $g(u) \oplus u_{2}$ | $g(u) \oplus\left(u_{1} \oplus u_{2}\right)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 0 | 1 | 1 | 0 | 1 | 1 | 1 | 0 | 0 |
| 1 | 0 | 1 | 0 | 1 | 1 | 0 | 1 | 0 |
| 1 | 1 | 1 | 0 | 0 | 1 | 0 | 0 | 1 |

where $0, u_{1}, u_{2}, u_{1} \oplus u_{2}$ are the possible linear function of $u_{1}$ and $u_{2}$ and

$$
d_{1}(g(u), 0)=3, \quad d_{2}\left(g(u), u_{1}\right)=1, \quad d_{3}\left(g(u), u_{2}\right)=1, \quad d_{4}\left(g(u), u_{1} \oplus u_{2}\right)=1
$$

So,

$$
N L_{g}=\min \left(d_{1}, d_{2}, d_{3}, d_{4}\right)=1
$$

## Definition 2.4.10.

If by changing single binary bit in an input results in significant change in an output, then the binary sequence is called Avalanche Effect [19].

When any algorithm shows higher AE, it means that algorithm is strong cryptographic and also secure against the attacks.

## Definition 2.4.11.

If single input bit is change as a result each output bit changes with the probability of 0.5 or $50 \%$ is called Strict Avalanche Criteria [19].

The values of Strict Avalanche Effect of S-box depend on the dependency matrix.

## Definition 2.4.12.

If single input bit changes as a result output bits will change independently is known as Bit Independence Criterion.

To measure the the relationship between pairs of avalanche variables, correlation must be calculated.

## Definition 2.4.13.

Linear Probability is used to compute the resistance of linear cryptanalysis, which is estimated as:

$$
\begin{equation*}
L P=\max _{\alpha_{z}, \beta_{z} \neq 0}\left|\frac{R\left\{z \in M \mid z \cdot \alpha_{z}=S(z) \cdot \beta_{z}\right\}}{2^{n}}-\frac{1}{2}\right| \tag{2.3}
\end{equation*}
$$

where $M$ represent the all possible inputs, $\alpha_{z}$ is the input bit and $\beta_{z}$ is output bit and $2^{n}$ with $n=8$ which is $2^{8}=256$ number of elements.

## Definition 2.4.14.

Differential Probability is use to measured the performance against differential cryptanalysis, which is estimated as:

$$
\begin{equation*}
D P=\max _{\Delta_{z} \neq 0, \Delta_{x}}\left(\frac{R\{z \in M \mid S(z) \oplus S(z \oplus \Delta z)=\Delta x\}}{2^{n}}\right) \tag{2.4}
\end{equation*}
$$

where $M$ represent the all possible inputs, $\Delta z$ is the input differentials, $\Delta x$ is output differentials and $2^{n}$ with $n=8$ which is $2^{8}=256$ number of elements. An Sbox with has lower Differential Probability can withstand differential cryptanalysis better.

Definition 2.4.15.

Take an S-box $P: G F\left(2^{n}\right) \rightarrow G F\left(2^{m}\right)$ and for $v \in G F\left(2^{n}\right)$. A point is called the fixed point of S-box if

$$
p(v)=v
$$

and the point is called the opposite fixed point of S-box if

$$
p(v)=v^{\prime}
$$

where $v^{\prime}$ is the reverse of $v$.
Any S-box is supposed to be good against differential cryptanalysis attacks which does not have fixed points and opposite fixed points as compared to those that has a fixed point and opposite fixed points.

## Example 2.4.16.

Take an S-box $(2 \times 2)$ with two Boolean functions as shown in Table 2.10
Table 2.10: S-Box of fixed point

| $G F(2)$ | Binary format of $G F(2)$ | S-Box | Binary format of S-Box |
| :---: | :---: | :---: | :---: |
| 0 | 00 | 1 | 01 |
| 1 | 01 | 3 | 11 |
| 2 | 10 | 2 | 10 |
| 3 | 11 | 0 | 00 |

In Table 2.10, the ' 2 ' element shows the fixed point of S-Box.

## Example 2.4.17.

Take an S-box $(2 \times 2)$ with two Boolean functions as shown in Table 2.11
Table 2.11: S-Box of opposite fixed point

| $G F(2)$ | Binary format of $G F(2)$ | S-Box | Binary format of S-Box |
| :---: | :---: | :---: | :---: |
| 0 | 00 | 1 | 01 |
| 1 | 01 | 2 | 10 |
| 2 | 10 | 3 | 11 |
| 3 | 11 | 0 | 00 |

In Table 2.11, the ' 1 ' element shows the opposite fixed point of S-Box.

### 2.5 Key Dependent S-Box

With the changing in technology day by day, people are searching for new features of data communication through the network with optimal data security. It is highly possible that during the transmission of data, information can be accessed by unauthorized individuals, putting any network systems security at risk [32]. However, the data security is more important and no risk is acceptable.

Substitution is the main source of nonlinearity in cipher block of symmetric cryptosystem and S-Box is only nonlinear part of cryptosystem. The primary weakness of symmetric ciphers is the existence of S-boxes, which are based on fixed (static) nature. Specified (fixed) substitution is the most obvious flaw in symmetric cryptosystems because it causes insecure ciphers due to the fixed and predefined qualities of diffusion and confusion [4]. Although permutation has its own effects, the essential building block of security in an encryption system is substitution.

Furthermore, static natured S-boxes do not depend on the secret key, so these static S-boxes are responsible for easy doorways for attackers to launch algebraic attacks. So there are need for design a S-boxes which are depend on key in order to resist differential and linear attack.

### 2.6 Software Tools in the Analysis of S-box

Some tools are available for the studying of S-box properties. A brief description of such available tools are given below:

## 1. Boolfun Package in $\mathbf{R}$

Free open source mathematical program is R, used for statistical computing. It runs on various windows UNIX and Mac OS platforum, despite the fact that the standard variant R does not support boolean function of evaluation, but a package name Boolfun can be loaded which gives feature related to cryptographic analysis of Boolean functions [33].

## 2. S-box Evaluation Tool (SET)

This technique for evaluating the cryptographic properties of the Boolean function and S-boxes was once proposed by Stjepan Picek and his team. SET stands for S-box Evaluation Tool. It is also a free tool for open source mathematics that is convenient and handy to use. It works in VS(visual studio) [34].

## 3. Sage Math

The Sage Math library is a free, open source mathematics tool that consists of a Boolean function module and an S-box. Through this method, we can test the algebraic properties and measure a range of cryptographic properties for S-boxes and Boolean functions associated to the linear approximation matrix and distinction distribution table.

## 4. VBF

VBF is the short form of Boolean Function Library Vector. It was introduced by Alverez-Cubero and Zufiria [35]. This tool is used for the test and analysis of cryptographic properties of S-boxes [35].

## 5. SAMT

SAMT is another tool for the analysis and evaluation of cryptographic properties of Boolean function and S-box. It works on MATLAB.

## Chapter 3

## Construction of Dynamic Key Dependent S-box for Symmetric Cryptosystem

S-box plays a significant role in cryptosystem. Recently a method is proposed by Ejaz et al. [19] for construction of dynamic key dependent secure S-boxes. In this chapter, a construction of S-box by using simple mathematical functions or operations are discussed. The operations used in S-box is given in Section 3.1. The proposed algorithm and flowchart of S-box is presented in Section 3.2. Findings and results of proposed S-box is given in Section 3.3 and the comparison between newly generated S-boxes of the proposed method are given in Section 3.4.

### 3.1 Operations Used for Generating S-box

There are number of methods of S-boxes proposed and designed by different researcher. Some researcher uses the static S-box for their research and some uses the dynamic S-box. But the analysis shows that the some S-boxes which are designed, either fixed (static) in nature, optimally not secure or deficient in dynamicity and
randomness due to which these are quiet vulnerable or exposed to the modern attack.

The proposed technique approach differs from previously developed AES based Sbox and its other variants since it does not employ affine polynomials to generate values for the S-box. The suggested substitution method makes use of a few straightforward yet essential mathematical operations or functions.

In the proposed method, S-boxes are constructed dynamically from secret key of 128-bits (16 bytes in Hexadecimal) by performing some basic and simple operations including Circular Shift, XOR and Nibble Swap.

Circular Shift is the operation of rearranging the entries in a tuple, either by moving the last entry to the first place, while moving all the other entries to the next place, or by performing the operation inverse. The some details are already discussed in Section 2.2. Formally, a permutation $\sigma$ is defined as a circular shift of entries n in each tuple such that:

$$
\sigma(j) \equiv(j+1) \quad \bmod m, \text { for all entries } j=1, \ldots, m
$$

Exclusive OR (XOR) is a logical operation that only produces a true value if certain conditions are met like one input is true and other input is false. Both inputs must be different. Its symbol is as follows:

$$
X \text { XOR } Y \text { is written as } X \oplus Y
$$

In Nibble Swap, the term nibble originally means "half an octet" or "half a byte". The terms 'byte' mean eight binary bits and 'nibble' mean four binary bits. In nibble swap operation, a byte is divided from middle into two nibbles and then each nibble shift with another. Some details are already discussed in Section 2.2.

The S-boxes produced by the proposed technique are entirely distinct from the fixed (static) S-boxes of AES since they are built using mathematical functions or operations to defend against algebraic attacks.

### 3.2 Proposed Algorithm for Generating S-box

Many researchers $[16,18,36,37]$ have proposed the design approaches of key dependent dynamic S-boxes generation with various cryptographic strengths. However, most of these approaches, lack in randomness and dynamicity. Ejaz et al. [19] proposed a secure key dependent dynamic substitution method for symmetric cryptosystem. This approach uses the simple mathematics operations and functions for creating S-box. The algorithm for designing S-box is explained below:

## Algorithm 3.2.1.

Input: Hexadecimal sequence input by the user, where Key $(K)=16$ characters

Output: S-box and Inv S-box

Step 1: Convert the 16 characters of $K$ (in Hexadecimal) into binary sequence of 128 bits of key then $K=128$ bits.

Step 2: Count the $n=$ number of $1 s$ from $K$ and perform the $n t h$ time left circular shift.

Step 3: Divide the $K=128$ bits into two halves, then

Left Key $(L K)=64$ bits and Right Key $(R K)=64$ bits

Step 4: Perform XOR operation on both halves. The resultant value are stored as $R^{\prime}$ and the previous Right Key $(R K)$ are stored as $L^{\prime}$.

Step 5: Convert the $R^{\prime}=64$ bits into 8 -bytes. After that perform nibble swap on each bytes.

Step 6: Store values (8-bytes) in array of size ' 8 ' followed by the loop. After that a conditional statement is used to avoid duplication and ensure uniqueness of S-box.

Step 7: After storing the values of $R^{\prime}$ in S-box, $R^{\prime}$ is reconverted into binary sequence of 64 bits.

Step 8: After that, both $L^{\prime}$ and $R^{\prime}$ rejoin here to make binary sequence of 128 bits, and then control moves back to the Step 1 as:

$$
K=L^{\prime}+R^{\prime}
$$

Step 9: Then, all actions are carried out in the previous order, and each step is managed by a conditional statement included within a conditional loop. This process is repeated until the S-box generates 256 distinct values in hexadecimal format.

Step 10: For inverse S-box, a new loop is generate in which the indexes and values of the generated S-box are swapped with each other to create the inverse S-box.

The Algorithm 3.2.1 implementation is performed on PC with MATLAB R2019b having operating system window 10 pro 64 bit, Core i7-4600U with 2.10 GHz CPU and 8GB Ram.

By taking as an Example of key in hexadecimal form, a S-box is constructed, which is shown in Table 3.1 and inverse S-Box is constructed, which is shown in Table 3.2.

## Example:

Key value (in hex): $7468617473206 D 79206 B 756 E 67206675$

Table 3.1: Key dependent dynamic S-Box

|  | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | $a$ | $b$ | $c$ | $d$ | $e$ | $f$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | $a 8$ | 08 | 26 | 38 | 24 | 10 | 16 | $d 1$ | $9 b$ | 60 | 58 | $a 2$ | 61 | $a a$ | $c 6$ | 82 |

| $c$ | $a 3$ | 92 | $e a$ | $c 0$ | $5 e$ | $f e$ | $0 e$ | $e d$ | $f 6$ | 18 | 70 | 47 | 98 | $f a$ | $5 b$ | $e 8$ |
| $d$ | $f 1$ | 07 | $c 3$ | $d 1$ | $4 c$ | $c 5$ | 29 | $7 e$ | $c 4$ | $9 e$ | $2 a$ | $2 b$ | 23 | 75 | $7 c$ | $d 0$ |
| $e$ | $9 c$ | $b 9$ | 90 | $b 5$ | $3 f$ | $c d$ | 56 | 45 | $3 c$ | $4 d$ | $9 a$ | $e b$ | $8 f$ | $a f$ | $7 d$ | 64 |
| $f$ | $f b$ | 73 | $d 9$ | 37 | $b 4$ | 61 | 20 | $d d$ | $a c$ | 39 | $e e$ | $c a$ | 86 | $f 2$ | 52 | 35 |

The generated S-box and inverse S-box values are in hexadecimal format. While the proposed approach is very useful and capable of producing endless S-boxes and their inverse S-boxes, only one example of an S-box and its inverse S-box are provided in Tables 3.1 and 3.2, respectively. The proposed method is key dependent and a single bit change in a key can produce various S-boxes with distinct values. Here is the flow diagram of the proposed method.

Set $\mathrm{i}=1$

Figure 3.1: Working flow of proposed substitution method

### 3.3 Finding and Result

The evaluation of constructed S-box in Table 3.1 is performed by using tool which is presented in [26]. Some cryptographic properties are describe in this section and some properties are also described in Chapter 2 is presented in this section.

### 3.3.1 Nonlinearity

Any good S-box should not map an input to an output linearly because it compromises the security of the cipher. The cipher is more resistant to linear cryptanalysis when the nonlinearity value is higher. The calculation formula for nonlinearity of S-boxes are already defined in Section 2.4.3. The average value of NL is 104.25 with a minimum of 102 and maximum of 108. The NL values of all eight component of the Boolean functions in proposed S-box is shown in Table 3.3.

Table 3.3: NL of Boolean function of proposed S-Box

| 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | Average |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 108 | 102 | 106 | 108 | 102 | 102 | 104 | 102 | 104.25 |

and the comparison of nonlinearity of S-box with previous S-boxes are shown in Table 3.4.

Table 3.4: Comparison of NL between proposed S-box with existing S-box

| S-boxes | NL |  |  |
| :--- | :---: | :---: | :---: |
|  | Min | Max | Avg |
| Hussain et al. [38] | 98 | 108 | 104 |
| Vaicekauskas et al. [39] | 98 | 108 | 102.5 |
| Alkhaldi et al. [40] | 98 | 108 | 104 |
| Hussain et al. [41] | 100 | 108 | 104.75 |
| Khan et al. [42] | 102 | 108 | 105.25 |
| Proposed [19] | 102 | 108 | 104.25 |

Thus the nonlinearity of S-box shows that it is a good indicator to resist the linear attack.

### 3.3.2 Strict Avalanche Criteria

Strict avalanche criteria is a necessary component for cryptographic S-box. This criterion indicates, if only single input changes as a result each output bit changes with the probability of 0.5 . The SAC values of S-box depend on dependency matrix. The average value of SAC is 0.504395 with a minimum of 0.406250 and maximum of 0.593750 . The dependency matrix for SAC of proposed method is shown in Table 3.5.

Table 3.5: Depedency matric for SAC

| 0.5625 | 0.5781 | 0.5000 | 0.5156 | 0.5156 | 0.5156 | 0.5468 | 0.5468 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 0.4531 | 0.4844 | 0.5312 | 0.4844 | 0.4531 | 0.4687 | 0.5156 | 0.5000 |
| 0.5468 | 0.5156 | 0.5156 | 0.5468 | 0.5468 | 0.4531 | 0.5000 | 0.4844 |
| 0.5156 | 0.4687 | 0.5312 | 0.5000 | 0.4218 | 0.5468 | 0.4687 | 0.4687 |
| 0.5468 | 0.5000 | 0.4687 | 0.4687 | 0.5000 | 0.5312 | 0.4687 | 0.5000 |
| 0.5781 | 0.5156 | 0.4687 | 0.4844 | 0.4844 | 0.4218 | 0.5625 | 0.4687 |
| 0.5937 | 0.4844 | 0.4844 | 0.5937 | 0.5781 | 0.4531 | 0.5468 | 0.5312 |
| 0.4062 | 0.4844 | 0.4218 | 0.5156 | 0.5468 | 0.4844 | 0.5000 | 0.4844 |

A comparison of minimum value, maximum value and average SAC value of the proposed S-box with the SAC values of existing S-boxes are shown in Table 3.6.

Table 3.6: Comparison of SAC between proposed S-box with existing S-box

| S-boxes | SAC |  |  |
| :--- | :---: | :---: | :---: |
|  | Min | Max | Avg |
| Jakimoski. [43] | 0.3761 | 0.5975 | 0.5058 |
| Khan et al. [42] | 0.3906 | 0.6250 | 0.5039 |
| Wang et al. [44] | 0.4850 | 0.5150 | 0.5072 |
| Çavuşoğlu et al. [45] | 0.4218 | 0.5937 | 0.5039 |
| Özkaynak et al. [46] | 0.3906 | 0.5703 | 0.4931 |
| Proposed [19] | 0.4062 | 0.5937 | 0.5044 |

Thus, the proposed method also meets the criteria of SAC and its values is close to 0.5 as compared with the others.

### 3.3.3 Differential Probability

Differential cryptanalysis for S-boxes was demonstrated by Biham and Shimar in [47]. Differential probability is use to measure the performance against the differential cryptanalysis and its formula is already defined in Section 2.4.3. Table 3.7 provides a summary of all the differential values of the proposed S-box.

Table 3.7: Differential approximation probability

| 0 | 8 | 8 | 6 | 6 | 6 | 8 | 8 | 8 | 6 | 10 | 6 | 8 | 8 | 6 | 8 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 6 | 6 | 8 | 8 | 6 | 6 | 6 | 10 | 6 | 6 | 8 | 6 | 8 | 6 | 8 | 6 |
| 6 | 8 | 8 | 6 | 8 | 8 | 6 | 8 | 6 | 10 | 6 | 6 | 6 | 8 | 6 | 8 |
| 8 | 8 | 6 | 6 | 10 | 6 | 6 | 8 | 6 | 8 | 6 | 8 | 8 | 6 | 6 | 6 |
| 8 | 8 | 6 | 6 | 8 | 6 | 6 | 6 | 6 | 8 | 6 | 8 | 6 | 6 | 8 | 6 |
| 6 | 6 | 8 | 6 | 6 | 6 | 6 | 6 | 6 | 8 | 6 | 6 | 10 | 6 | 10 | 8 |
| 6 | 8 | 6 | 8 | 6 | 6 | 6 | 6 | 6 | 8 | 6 | 6 | 6 | 8 | 8 | 6 |
| 6 | 6 | 6 | 6 | 6 | 8 | 8 | 8 | 8 | 6 | 6 | 6 | 6 | 6 | 6 | 8 |
| 6 | 6 | 4 | 6 | 8 | 8 | 8 | 6 | 8 | 8 | 10 | 6 | 8 | 6 | 6 | 6 |
| 6 | 6 | 10 | 6 | 8 | 8 | 6 | 6 | 8 | 6 | 6 | 6 | 6 | 4 | 8 | 8 |
| 6 | 6 | 6 | 8 | 6 | 6 | 8 | 8 | 6 | 6 | 6 | 8 | 6 | 8 | 6 | 6 |
| 6 | 8 | 8 | 6 | 6 | 6 | 8 | 8 | 6 | 6 | 6 | 6 | 8 | 8 | 8 | 6 |
| 6 | 8 | 8 | 6 | 6 | 10 | 6 | 8 | 6 | 6 | 6 | 6 | 8 | 6 | 6 | 6 |
| 6 | 8 | 6 | 6 | 6 | 6 | 10 | 8 | 8 | 6 | 6 | 8 | 8 | 10 | 6 | 6 |
| 6 | 6 | 10 | 8 | 8 | 6 | 8 | 6 | 8 | 6 | 6 | 6 | 4 | 6 | 6 | 6 |
| 6 | 8 | 8 | 10 | 8 | 6 | 6 | 8 | 6 | 6 | 6 | 6 | 6 | 6 | 8 | 8 |

The maximum value in Table 3.7 is 10, which only appears thirteen times in the Table. When 10 is divided by 256 , the value of DP is equal to 0.03906 . Table 3.8 displays the comparison of S-box values with other DP values.

Table 3.8: Comparison of DP between proposed S-box with existing S-box

| S-boxes | Khan et al. [42] | Wang et al. [44] | Özkaynak et al.[46] | Proposed [19] |
| :--- | :---: | :---: | :---: | :---: |
| Max DP | 0.03906 | 0.0468 | 0.0468 | 0.03906 |

Thus, the proposed method is strong enough to withstand the differential attack.

### 3.3.4 Bit Independence Criterion

A function $(g)$ justifies the bit-independence criterion for the input ( $u$ ) and output $(v, w)$ in such a way that if the input bit $(u)$ is changed then the output bits $(v, w)$ should change independently. Correlation must be calculated to measure relationship between the avalanche variable sets. The average value of BIC-NL is 103.857 with a minimum of 96 and maximum of 108 . The BIC-NL of the proposed S-box method is shown in Table 3.9.

Table 3.9: BIC-NL

| - | 100 | 106 | 102 | 102 | 104 | 102 | 106 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 100 | - | 102 | 108 | 104 | 98 | 104 | 106 |
| 106 | 102 | - | 96 | 102 | 106 | 106 | 106 |
| 102 | 108 | 96 | - | 104 | 106 | 108 | 104 |
| 102 | 104 | 102 | 104 | - | 98 | 104 | 106 |
| 104 | 98 | 106 | 106 | 98 | - | 106 | 106 |
| 102 | 104 | 106 | 108 | 104 | 106 | - | 106 |
| 106 | 106 | 106 | 104 | 106 | 106 | 106 | - |

The comparison of BIC-NL values of proposed S-box with the existing S-box methods are shown in Table 3.10.

Table 3.10: Comparison of BIC-NL between proposed S-box with existing S-box

| S-boxes | Çavuşoğlu et al.[45] | Khan et al.[42] | Alkhaldi et al.[40] | Proposed[19] |
| :--- | :---: | :---: | :---: | :---: |
| BIC-NL | 103.3 | 100.3 | 102.9 | 103.857 |

Thus, it shows that the proposed S-box method significantly justifies nonlinearity based bit independence criterion.

### 3.3.5 Linear Probability

The linear probability was introduced in 1993 to break the 8-rounds of Data Encryption Standard [48]. The use of LP is to compute the resistence of the linear cryptanalysis and its formula is already defined in Section 2.4.3. Maximum LP of proposed S-box is just 0.1328, indicating that it is resistant to linear cryptanalysis.

Table 3.11 shows the maximum LP value and its comparison with maximum LP value of earlier S-Box methods.

Table 3.11: Comparison of LP between proposed S-box with existing S-box

Thus, the comparison shows that proposed method is effective and resistant to linear attacks.

### 3.3.6 Difference Percentage

This is a very important factor in analyzing the strength of S-boxes. This test analyzes that if only single bit of key is changed, then how many values are relocated to distinct position than previously generated S-box. Another important feature of this test is that it enhances the avalanche effect and enhances safety. To conduct this test, many S-boxes were created using various keys, and then further S-boxes were created by altering one bit of each key from various keys. Then all the newly S-boxes which were generated compared with previous S-boxes. But the proposed method can generate a new S-box with a unique value by only changing in one bit of the input key.

Table 3.12 shows the newly generated S-box with different key, where the key is 747366792075207475 6B 206761 6E 6D 68

Table 3.12: New S-Box by changing key

|  | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | $a$ | $b$ | $c$ | $d$ | $e$ | $f$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 08 | 32 | 80 | $3 c$ | $8 c$ | 96 | $3 a$ | 19 | $0 a$ | 53 | $7 e$ | 76 | $d 9$ | 14 | $1 e$ | $a e$ |
| 1 | 63 | 98 | 44 | 82 | $d 0$ | $a 1$ | 87 | 40 | $f 2$ | $a 0$ | $a 3$ | 93 | 13 | $0 e$ | $1 f$ | 60 |

| 3 | $c 5$ | $a a$ | $6 d$ | $c 9$ | $e 9$ | $c b$ | 00 | 90 | 28 | 46 | 77 | 22 | 65 | 21 | 95 | $7 b$ |
| 4 | 62 | 49 | $f 1$ | $9 c$ | $b a$ | 10 | 01 | $c 0$ | $4 d$ | $5 c$ | $e 8$ | $d 2$ | $e e$ | $2 b$ | $6 e$ | 72 |
| 5 | $e d$ | $4 a$ | $2 a$ | $c 4$ | $b 3$ | $5 d$ | $2 d$ | $6 f$ | $f f$ | $7 a$ | $a 4$ | $f a$ | $e 5$ | 37 | $a 6$ | 92 |
| 6 | $6 c$ | $f 3$ | 83 | $e f$ | $a 9$ | $e 4$ | $f 7$ | 74 | $7 c$ | $0 b$ | $b 9$ | $9 a$ | $f 5$ | $e 2$ | $f 6$ | 59 |
| 7 | $f 9$ | 75 | 17 | 47 | $2 e$ | 61 | $b b$ | $5 f$ | $c 6$ | 85 | $0 d$ | 02 | 55 | $5 e$ | 50 | $d e$ |
| 8 | $f b$ | $4 f$ | $0 c$ | 97 | 73 | 78 | $3 f$ | $c c$ | 52 | $e c$ | 04 | 64 | $b c$ | 88 | 84 | $3 d$ |
| 9 | 86 | $c 3$ | 45 | $e 7$ | 48 | 23 | $5 b$ | $e 6$ | $d 5$ | 16 | $8 e$ | $3 b$ | $3 e$ | $b 5$ | $4 c$ | $d 7$ |
| $a$ | 33 | $d 4$ | $9 b$ | $b 6$ | $8 b$ | $c 2$ | $a 7$ | 39 | $d d$ | 89 | 07 | 56 | $b 4$ | $b e$ | $d 1$ | 15 |
| $b$ | $a b$ | $a c$ | $d 6$ | $e 1$ | $c a$ | $c 1$ | $7 d$ | $a 5$ | $f e$ | $4 b$ | 05 | $5 a$ | $d 3$ | 58 | $6 b$ | 24 |
| $c$ | $c 7$ | $d f$ | $c 8$ | $9 f$ | $c d$ | 29 | $2 c$ | 36 | $1 d$ | $f 4$ | 41 | $f d$ | 68 | 03 | 18 | $d a$ |
| $d$ | $a f$ | $d c$ | $f 0$ | 79 | 11 | 30 | $e a$ | 94 | 51 | 26 | $d 8$ | $2 f$ | $f 8$ | 57 | $8 f$ | 12 |
| $e$ | 27 | $1 c$ | 81 | $0 f$ | $f c$ | $b f$ | 54 | 42 | $1 b$ | $b 0$ | 67 | $e b$ | $d b$ | 66 | 43 | $4 e$ |
| $f$ | 69 | $b 7$ | $9 e$ | $a 2$ | $b 1$ | $a d$ | $e 0$ | 70 | 71 | $c e$ | 38 | $8 a$ | 99 | 31 | 91 | $b d$ |

The comparison of Tables 3.1 and 3.12 demonstrates that, even after changing the key, the generation of new S-boxes using the suggested method fully satisfies the criteria of difference percentage.

### 3.3.7 Other Properties of S-box

Here are the result of some other properties of proposed S-box. These properties are described in Chapter 2.

- S-box is Bijective.
- The number of fixed point is 1 and opposite fixed point of $S$-box is 3 .
- S-box is Balanced.
- Algebraic degree is 7 .
- Bent nonlinearity value of S-box is 116.6863 .
- Hamming weight of all Boolean functions of S-box are given below:

| $S_{j}$ | $S_{1}$ | $S_{2}$ | $S_{3}$ | $S_{4}$ | $S_{5}$ | $S_{6}$ | $S_{7}$ | $S_{8}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $H W$ | 128 | 128 | 128 | 128 | 128 | 128 | 128 | 128 |

### 3.4 Comparison Between Newly Generated Sboxes of Proposed Method

With the help of proposed method, different S-boxes were generated with different keys and their values of different properties was calculated. The few generated different S-boxes are given in Appendix A and there calculated values are given below:

TABLE 3.13: Different properties of newly generated S-boxes

|  |  |  |  |  |  |  |  |  |  |  |

Table 3.13 shows the values of different S-boxes which are generated through proposed method in which the highest $\operatorname{AvgNL}$ value is 106 and lowest AvgNL value is 101.25 , the highest DP value is $14 / 256$ which is 0.0546 and lowest DP value is
$10 / 256$ which is 0.03906 , the highest LP value is 0.1484 and lowest LP value is 0.1172 , the highest BIC-NL value is 104.500 and lowest BIC-NL value is 102.071 and the SAC value are close to 0.5 .

Thus, this shows that the proposed technique can produce several S-boxes with good properties.

## Chapter 4

## Application of S-box in Cryptography

An S-box (substitution-box) is a fundamental building block of symmetric key algorithms in cryptography that performs substitution. They usually serve to ensure Shannon's property of confusion in block ciphers by masking the connection between the key and the ciphertext. The performance and security level of an encryption method are directly impacted by the substitution box, which is the nonlinearity component of a symmetric key encryption technique. In this chapter, an efficient and secure method is proposed for dynamic S-box and chaos keygenerator based image encryption scheme.

### 4.1 Chaos Theory

Chaos is the study of unexpected and nonlinear surprises. That is a simple technique to foresee the unexpected. Chaos theory is the branch of mathematics concerned with the behaviour of dynamic systems. Weather, stock market volatility, our mental states, and other nonlinear processes that are difficult to stabilize or regulate are all covered by the chaos theory. Almost all chaos-based cryptographic algorithms employ dynamic systems based on a set of real numbers, which are
challenging for practical realization and circuit implementation. Chaos cryptography refers to the use of chaos in secret writing. The study of a quick secure system design is known as chaos cryptography. The system dynamics can function in a guaranteed state of chaos, as determined by the traffic model. A dynamic system is one whose operation depends on a time-dependent point in a geometrical space, such as the motion of a pendulum or the flow of water through a pipe. Any map that exhibits chaotic activity is said to as chaotic. The time parameter could be discrete or continuous. Discrete maps are appropriate forms of iterated functions.

### 4.1.1 Properties of Chaotic System

In practically all nonlinear deterministic systems, the chaos phenomenon can be encountered. When long-term mathematical function progresses in a continuous and haphazard manner, chaos appears to exist. Chaotic systems include the following characteristics:

## - Apparently arbitrary but totally deterministic behaviour

Although the behaviour of a chaotic system seems random but it is completely predictable. Therefore, the same output value set is produced by an iterative chaotic system with the identical initial conditions.

## - Long-term Prediction

Small variations in the initial conditions, such as those brought on by measurement mistakes or rounding errors in numerical computation, can result in dramatically different results for these dynamical systems making long-term prediction is generally challenging.

## - Sensitivite to Initial Conditions

Sensitivity to initial conditions implies that a systems behaviour might diverge quickly due to slightly altered conditions, making it unpredictable.

### 4.1.2 Lyapunov Exponent

In the study of dynamical systems, the term "Lyapunov Exponent" has been frequently used [49]. LE describes the degree of divergence between two closely spaced dynamical system trajectories. A positive LE means that the two trajectories diverge more and more with each iteration until they are completely different, regardless of how close they are to one another. The LE of a chaotic dynamical system is hence positive. The number of LE in a multidimensional dynamical system may be many. Its close paths exponentially diverge in various dimensions if it has more than one positive LE. Hyperchaotic behaviour is the term given to this occurrence. The performance of a dynamical system with hyperchaotic behaviour is very high in terms of chaos, and the results are unpredictable. LE can be defined as:

$$
\begin{equation*}
\lambda=\lim _{n \rightarrow \infty} \frac{1}{n} \sum_{i=0}^{n-1} \ln \left|g^{\prime}\left(y_{i}\right)\right| \tag{4.1}
\end{equation*}
$$

where $g\left(y_{i}\right)$ is the chaotic system's function. There are three dynamical scenarios for the LE.

1. All LE are less than zero if the orbit attracts toward a stable point.
2. The system is neutrally stable when the LE is zero such system are conservative and in a steady state mode. They display Lyapunove stability.
3. All LE are greater than zero if the system is chaotic.

### 4.1.3 Bifurcation Diagram

A bifurcation, also known as a period doubling or transition from an $M$-point attractor to a $2 M$-point attractor, takes place when the control parameter is changed. A bifurcation diagram is a visual representation of the series of period-doubling that take place as the control parameter $r$ rises. Figure 4.1 shows the bifurcation
diagram of logistic chaotic map, with $r$ as the horizontal axis. The system is allowed to settle for each value of $r$ before plotting successive values of $x$ over a few hundred iterations.

### 4.1.4 Logistic Map

One of the most well-known 1D chaotic maps is the logistic map, which has a straightforward mathematical foundation but complex chaotic behaviour. The logistic map's mathematical representation is

$$
\begin{equation*}
x_{n+1}=r x_{n}\left(1-x_{n}\right) \tag{4.2}
\end{equation*}
$$

where $r$ is the control parameter and $x_{n}$ is the initial condition of the equation (4.2).

Figure 4.1: Bifurcation Diagram of Logistic map

Figure 4.1 makes it obvious that every point is shown at zero when the value is $r \leq 1$. As a result, there is only one point attractor for $r \leq 1$. There are still one point attractors for $r \in(1,3)$, but the value of $x$ that is attracted increases as $r$ rises. Bifurcation occurs at $r=3,3.45,3.54,3.564,3.569$, etc. up until immediately after 3.57 is the point at which chaos takes over. However, the system
is not chaotic for all values of $r \in[3.57,4]$, and there are some points where three point attractors are visible.

### 4.1.5 Tent Map

Tent map is a 1D discrete chaotic iterative map that displays tent-like shape. It is also referred to as a triangular map. The following is mathematical model of tent map:

$$
x_{n+1}=\left\{\begin{array}{ccc}
\mu x_{n} & \text { if } & 0<x_{n}<0.5  \tag{4.3}\\
\mu\left(1-x_{n}\right) & \text { if } & 0.5 \leq x_{n}<1
\end{array}\right.
$$

where $\mu \varepsilon[0,2]$ is the control parameter which takes a positive real number and $x_{0} \varepsilon[0,1]$ is the initial condition of equation (4.3).

Figure 4.2 shows bifurcation diagram which reveals the following details. For $\mu \varepsilon[0,1)$ the equation converges to $x=0$ in the tent map, which has one fixed point at $x=0$. For $\mu=1$ all values of $x \leq 0.5$ are fixed points of system. For $\mu$ between 1 and 2, the system produces an unstable, chaotic sequence. Tent map exhibits fixed point behaviour when the $\mu<1$ and chaotic behaviour when the $\mu>1$.

Figure 4.2: Bifurcation Diagram of Tent map

The logistic map and tent map both experienced issues with the output state values being distributed unevenly and having a tiny chaotic range.

### 4.1.6 The Tent Logistic system

Lu et al. [50] developed the tent-logistic system, a new compound system that combines the tent and logistic map, to address the problems with the logistic and tent maps (TLS). This is its mathematical model:

$$
x_{n+1}=\left\{\begin{array}{cc}
\frac{4(9-\mu)}{9} x_{n}\left(1-x_{n}\right)+\frac{2 \mu}{9}\left(x_{n}\right) & x_{n}<0.5  \tag{4.4}\\
\frac{4(9-\mu)}{9} x_{n}\left(1-x_{n}\right)+\frac{2 \mu}{9}\left(1-x_{n}\right) & x_{n} \geq 0.5
\end{array}\right.
$$

where $\mu \in[0,9]$ is the control parameter. When $\mu=0$, the above equation behaves as a logistic map; however, when $\mu=9$, it degenerates into a tent-shaped chaotic map. Figure 4.3 displays the TLS bifurcation diagram. It is clear from Figure 4.3 that the chaotic range was significantly greater than the logistic or tent map ranges, being the entire range $[0,9]$. Its output sequences are uniformly distributed. Therefore, compared to the logistic and tent maps, the TLS performed better under chaotic conditions.

Figure 4.3: Bifurcation Diagram of Tent-Logistic map

In comparison to logistic and tent maps, the tent-logistic approach has two advantages. First, the tent-logistic system's chaotic range was significantly larger than
that of the logistic and tent maps. If the system parameter was used as the cryptosystem secret key, the key space of the cryptosystem based on the new system would be significantly bigger. Second, over the entire 0 to 1 value range, the tentlogistic system had equally spaced output sequences. These advantages made the suggested tent-logistic technique more appropriate for cryptography applications.

### 4.2 Proposed Cryptosystem for Image Encryption

In this section, we go over the detailed process for both the proposed image encryption and decryption utilizing chaotic tent-logistic system and S-box. S-box is generated through the Algorithm 3.2, used as a lookup table for the replacement of pixels. Then the three chaotic sequences are generated and the bitwise XOR operation is implemented with substituted pixel values of each image component. Figure 4.4 show the flow diagram of proposed algorithm.

### 4.2.1 Key management

An external secret key is used for generating initial condition of chaotic map. The 128 -bit form of the external secret key is represented by

$$
\begin{equation*}
W(i)=w_{127} w_{126} \cdots w_{0} \tag{4.5}
\end{equation*}
$$

and

$$
\begin{equation*}
W_{i}=k_{1} k_{2} \cdots k_{16} \tag{4.6}
\end{equation*}
$$

Each $k_{i}$ is an 8 bit block of the secret key. From the above blocks, the following unique initial condition $x$ and three parameters $\mu_{1}, \mu_{2}, \mu_{3}$ are derived:

$$
\begin{equation*}

and
$\mu_{1}=\left(w_{1} \times 2^{3}+w_{2} \times 2^{2}+w_{3} \times 2^{1}+w_{4} \times 2^{0}+w_{5} \times 2^{-1}+\cdots+w_{11} \times 2^{-7}\right) \quad \bmod 9$
$\mu_{2}=\left(w_{12} \times 2^{3}+w_{13} \times 2^{2}+w_{14} \times 2^{1}+w_{15} \times 2^{0}+w_{16} \times 2^{-1}+\cdots+w_{22} \times 2^{-7}\right) \quad \bmod 9$
$\mu_{3}=\left(w_{23} \times 2^{3}+w_{24} \times 2^{2}+w_{25} \times 2^{1}+w_{26} \times 2^{0}+w_{27} \times 2^{-1}+\cdots+w_{33} \times 2^{-7}\right) \quad \bmod 9$

## Algorithm 4.2.1. (Image encryption algorithm)

Input: Image $I$, Algorithm 3.2, Secret key $k$, Tent Logistic map

Output: Encrypted image $C$

Step 1: Read the provided image $I$.

Step 2: Separate the colour image $I$ into its Red, Green, and Blue (RGB) primary colour components.

Step 3: Input 128 bits secret key (16 hexadecimal) in Algorithm 3.2 to generate an S-box.

Step 4: Use S-box(1D) as lookup table and apply on every component of image $I$ to get the substitution.

Step 5: Convert the substituted colour components into a one-dimensional array.

Step 6: Iterate the tent-logistic map for $L$ times with the initial state $x$ and the control parameters $\mu_{1}, \mu_{2}, \mu_{3}$ to generate three chaotic sequences.

Step 7: To remove the negative effects of transient process, discard the first $n_{0}$ values from $L$, i.e., $L 1=L-n_{0}$.

Figure 4.4: Flow diagram of proposed image encryption

Step 8: Apply the below given relations to transform the obtained sequence into 8-bit integer values

$$
\begin{aligned}
x_{i} & =\bmod \left(\text { floor }\left(x_{i} \times 10^{14}\right), 256\right), i=1,2, \ldots, L 1, \\
y_{i} & =\bmod \left(\text { floor }\left(y_{i} \times 10^{14}\right), 256\right), i=1,2, \ldots, L 1, \\
z_{i} & =\bmod \left(\text { floor }\left(z_{i} \times 10^{14}\right), 256\right), i=1,2, \ldots, L 1,
\end{aligned}
$$

where floor $(x)$ returns the greatest integer less than or equal to $x$ and mod returns the residual after dividing by 256 . As a result, the output sequences fall within the $[0,255]$ range.

Step 9: Using the previously created chaotic sequence, diffuse each colour component's separability as follows:

For red component:

$$
\begin{gathered}
R^{\prime}(1)=R(1) \oplus x(1) \quad \bmod 256 \\
R^{\prime}(i)=\left((R(i) \oplus x(i)) \oplus R^{\prime}(i-1)\right) \quad \bmod 256 \quad ; 2 \leq i \leq L 1
\end{gathered}
$$

For green component:

$$
\begin{gathered}
G^{\prime}(1)=G(1) \oplus y(1) \quad \bmod 256 \\
G^{\prime}(i)=\left((G(i) \oplus y(i)) \oplus G^{\prime}(i-1)\right) \quad \bmod 256 \quad ; 2 \leq i \leq L 1
\end{gathered}
$$

For blue component:

$$
\begin{gathered}
B^{\prime}(1)=B(1) \oplus z(1) \quad \bmod 256 \\
B^{\prime}(i)=\left((B(i) \oplus z(i)) \oplus B^{\prime}(i-1)\right) \quad \bmod 256 \quad ; 2 \leq i \leq L 1
\end{gathered}
$$

Step 10: Convert the obtained $R^{\prime}, G^{\prime}$ and $B^{\prime}$ components into two dimensional array and combine these color components to get the ciphered image C .

The following decryption algorithm can be used to restore the original image of the cipher image C .

## Algorithm 4.2.2. (Image decryption algorithm)

Input: Cipher image $C$, Algorithm 3.2, Secret key $k$, Tent Logistic map

Output: Original image $I$

Step 1: Read the cipher image $C$.

Step 2: Separate the cipher image $C$ into its Red $\left(R^{\prime}\right)$, Green $\left(G^{\prime}\right)$, and Blue $\left(B^{\prime}\right)$ primary colour components.

Step 3: Convert the colour components into a one-dimensional array.

Step 4: Iterate the tent-logistic map for $L$ times with the initial state $x$ and the control parameters $\mu_{1}, \mu_{2}, \mu_{3}$ to generate three random sequences.

Step 5: To remove the negative effects of transient process, discard the first $n_{0}$ values from $L$, i.e., $L 1=L-n_{0}$.

Step 6: Apply the below relation to transform the obtained sequence into 8-bit integer values

$$
\begin{aligned}
& x_{i}=\bmod \left(\text { floor }\left(x_{i} \times 10^{14}\right), 256\right), i=1,2, \ldots, L 1, \\
& y_{i}=\bmod \left(\text { floor }\left(y_{i} \times 10^{14}\right), 256\right), i=1,2, \ldots, L 1, \\
& z_{i}=\bmod \left(\text { floor }\left(z_{i} \times 10^{14}\right), 256\right), i=1,2, \ldots, L 1,
\end{aligned}
$$

where floor $(x)$ returns the greatest integer less than or equal to $x$ and mod returns the residual after dividing by 256 . As a result, the output sequences fall within the $[0,255]$ range.

Step 7: Using the previously created chaotic sequence, decrypt each colour component's separability as follows:

For red component:

$$
\begin{gathered}
R(i)=\left(\left(R^{\prime}(i) \oplus x(i)\right) \oplus R^{\prime}(i-1)\right) \quad \bmod 256 \quad ; 2 \leq i \leq L 1 \\
R(1)=R^{\prime}(1) \oplus x(1) \quad \bmod 256
\end{gathered}
$$

For green component:

$$
\begin{gathered}
G(i)=\left(\left(G^{\prime}(i) \oplus y(i)\right) \oplus G^{\prime}(i-1)\right) \quad \bmod 256 \quad ; 2 \leq i \leq L 1 \\
G(1)=G^{\prime}(1) \oplus y(1) \quad \bmod 256
\end{gathered}
$$

For blue component:

$$
\begin{gathered}
B(i)=\left(\left(B^{\prime}(i) \oplus z(i)\right) \oplus B^{\prime}(i-1)\right) \quad \bmod 256 \quad ; 2 \leq i \leq L 1 \\
B(1)=B^{\prime}(1) \oplus z(1) \quad \bmod 256
\end{gathered}
$$

Step 9: Convert the obtained $R, G$ and $B$ components into two dimensional array.

Step 10: Input 128 bits secret key (16 hexadecimal) in Algorithm 3.2 to generate an S-box and then its inverse S-box(1D).

Step 11: Use inverse S-box as lookup table and apply on the every component of cipher image $C$ and combine these color components to get the original image $I$.

### 4.3 Results and Discussion

The experimental findings are presented in this section. For the verification of our scheme, colour images named as Lena and aeroplane are taken. Results of the proposed scheme are shown in the Figure 4.5.

Figure 4.5: Experimental result for Original images of Lena (a) and aeroplane (d), Encrypted image (b) and (e), Decrypted image (c) and (f)

### 4.3.1 Performance Analysis

We applied the some popular security test to check the resistance of the several attacks to the proposed scheme. For this purpose, image of Lena of same size (256 $\times 256$ ) are used.

- Statistical Analysis

A secure cryptosystem must resist different types of attacks efficiently. For examining the resistance of proposed cryptosystem, we use the histogram test, key space analysis, key sensitivity, correlation coefficient and entropy test.

### 4.3.1.1 Histogram Test

The pictorial representation of each pixel intensity value and their frequencies is known as histogram [51]. A good encryption scheme should always give a cipher
image with a uniform histogram distribution for any plain images. Figure 4.6a, 4.6 b and 4.6 c show the red, green and blue components of histogram of original image and Figure 4.6d, 4.6e and 4.6 f give the histogram of encrypted image. It is clear that the histogram of encrypted image is different from the histogram of the original image and the histogram of cipher image is almost uniform then we conclude that the attacker cannot break the security of the proposed method.

Figure 4.6: Histogram of Original image red component (a) Original image green component (b) Original image blue component (c) Encrypted image red component (d) Encrypted image green component (e) Encrypted image blue component (f)

### 4.3.1.2 Key Space Analysis

To prevent a brute force attack, a good encryption method should have a large key space. The suggested technique uses a 128 -bit key. It includes $2^{128}$ distinct keys combinations. Therefore, the proposed scheme ensures a sufficiently large key space which are greater than $2^{104}$ to prevent the brute force attack.

### 4.3.1.3 Correlation Coefficient

Correlation means the relation of the neighbouring pixels in horizontal, vertical and diagonal directions. In digital images, pixels are highly correlated with each other. A cryptosystem is considered good if its break this strong correlation by applying the encryption algorithm [23]. Table 4.1 shows the correlation of the original image and encrypted images.

The value of correlation coefficient falls between the -1 and 1 . In contrast to the -1 value, which indicates a decreasing linear relationship, the 1 value indicates an increasing linear relationship. The value " 0 " indicates that the two images are independent. Table 4.1 demonstrates that the correlation coefficient of the suggested technique is close to the zero, indicating that the plain image and cipher image are not linearly related with one another.

Table 4.1: Correlation coefficient of two neighbouring pixels

| Scheme | Vertical | Horizont | Diagonal |
| :---: | :---: | :---: | :---: |
| Original Image | 0.9804 | 0.9585 | 0.9425 |
| Encrypted Image | -0.0042 | 0.0010 | -0.0020 |
| Supriyo et al. [23] | 0.0022 | 0.0026 | -0.0008 |
| Hafsa et al. [52] | -0.006 | -0.0003 | 0.00014 |
| Abduljabbar et al.[53] | 0.0070 | 0.0033 | 0.0027 |

### 4.3.1.4 Key Sensitivity

In general, the key sensitivity means that a minor change in the keys would generate unique different cipher images. A good image encryption algorithm should be

Figure 4.7: Key sensitivity analysis for Original image (a) and (d), Encrypted image (b) and (e), Decrypted image with slightly wrong key (c) and (f)
very sensitive to key that is utilized [54]. Suppose a key is obtained by changing the single bit of the original key. Then by the sensitivity of keys, we assume that the original image will not reveal because we change the original key. Suppose we consider the new key '7468617473206D79206B756E67206676'. Figure 4.7a and 4.7 d indicate the original images, 4.7 b and 4.7 e indicate the encrypted images by using original key and 4.7c and 4.7 f show the decrypted images after changing the key. Thus 4.7 c and 4.7 f indicate that the original images are not revealed. Hence, the proposed scheme is sensitive to key.

### 4.3.1.5 Entropy Test

It is a measuring tool to decide the level of irregularity of a data sequence. An ideal random data of 8 bit sequence should achieve the entropy value 8 [23]. It is a fundamental and efficient test for actually looking at whether the pixels of the encrypted images are arbitrary or not. Table 4.2 shows the values of plain image and cipher image.

It is clear that all the entropy values are close to 8 , thus the proposed cryptosystem is appropriate for making high randomness in cipher images.

Table 4.2: Entropy Test

| Encrypted Scheme | Entropy value |
| :--- | :---: |
| Encrypted Image | 7.9990 |
| Supriyo et al. [23] | 7.9990 |
| Hafsa et al. [52] | 7.9998 |
| Abduljabbar et al.[53] | 7.99913 |

## Chapter 5

## Conclusion

In this thesis, reviewed of the scheme [19] based on key dependent S-box is discussed. This scheme used the simple functions like circular shift, XOR and nibble swap. The key used for generating S-box has 128 bits long. A straightforward and efficient method is used to build the S-box. The analysis shows that the constructed S-box has a good cryptographic properties.

Then we use this key dependent S-box in our image encryption scheme. In encryption phase, S-box is used for the confusion purpose and the compound chaotic map (tent-logistic map) is used for generating chaotic sequence. After that, a mixing technique was used to combine the values of the substituted image pixels with the generated sequence to get the cipher image. The decryption procedure is similarly the inverse of the encryption procedure. We obtained the plain image by reverse the order.

The suggested algorithm has offered resistance against various cryptographic attacks. The efficiency of the suggested method is demonstrated by the security analysis.

As a future work, the proposed scheme by Ejaz et al. [19] can be extended to 192 or 256 bits of different sizes of key and then the generated S-boxes can be used in image encryption scheme.
